

I've been thinking of some of the different ways in which real world AI and automation may be able to remove friction from the day to day operations of Fin Tek, without changing what or how Fin Tek does things. I'm not talking about changing the operational structure of the company, I am talking about removing friction when it comes to scheduling, communication, and information/knowledge sharing so Fin Tek can focus on its core strengths of technical and engineering activities.

Tier 1: Immediate, low-risk help (30-90 days)

1. Automate Routine Emails, Reminders & Follow-ups

With simple automation, I could assist with many of your typical incoming customer communications (emails & service requests), confirm appointments, and remind customers about scheduled services, in addition to sending automated follow-up communications for service calls. As a result, most of the routine communication would be handled by AI, reducing the time required to repeatedly go back and forth with customers.

Additionally, I can create a quick summary on a daily/weekly basis to show your overall email and message activity, including number of new messages received, number of automatic responses sent vs. messages escalated to humans, major customers contacted, and any follow-up communications needed. The purpose of this tool would be similar to Fin-Tek's AI assistant - it will serve to assist with customer communication, while providing transparency and making it easier to review.

2. Scheduling and dispatch assistance

I could build lightweight tools to help organize technician schedules, highlight which service calls should be given top priority, and reduce the frustration that comes with coordinating everything. This would support and enhance how scheduling is done today rather than replacing your current process.

3. Internal Knowledge Assistant For Technicians

I can develop an internal search tool for techs to use to quickly find information contained within manuals, procedures and past service notes using everyday language. This will enable techs to resolve issues more efficiently in the field and will allow for less reliance on tribal knowledge.

4. Financial insight and day to day bookkeeping summaries

I could also help set up lightweight tools that provide better visibility into day to day financial items such as outstanding invoices, upcoming bills due, overdue payments, and receipt tracking. This would not replace any existing accounting or bookkeeping systems. Instead, it would add a simple layer of summaries and reminders so important items are easier to see and less time is spent digging through emails or systems to find what needs attention.

5. Parts and inventory forecasting

Once there is a solid foundation of usable data, I could help predict parts usage based on past service history so that ordering becomes more predictable and emergency rush orders are reduced.

6. Predictive maintenance longer term

Over time, service and performance data could potentially be used to anticipate equipment issues before they occur. This is a longer term initiative, but if successful, it could eventually support more proactive and higher value preventative maintenance offerings.

My hope would be to start small, demonstrate a clear return on investment, and only expand the efforts that clearly save time or money. I would be happy to talk through any of these ideas with you and see if there is something that feels worth trying.
